## AMSC/MATH 420, Spring 2015 First Solo Homework: Fitting Linear Statistical Models to Data

Due Tuesday, February 3

A dataset consisting of the national total numbers of births in the US on each day in 2003 can be found on the course web page as a text file births2003.txt. Using these data:

- (a) Show that there is an important day-of-the-week effect on the way these numbers of births turn out. Which days of the week regularly have the smallest numbers of births?
- (b) Demonstrate graphically that after subtracting a quantity that depends only on the day of the week, either from the numbers of births or from their logarithms, what remains is a sequence of numbers that looks more or less like a curvilinear trend plus "noise" except for relatively few anomalous days. Here "noise" means an apparently patternless sequence of numbers which, either visually or by some other criterion, looks like a sequence of independent, identically distributed values across time.
- (c) Identify and examine the anomalous days in (b). Was there anything special about these days in 2003 that might help account for anomalies?
- (d) Using a linear least-squares fit, express as simply and smoothly as possible the common curvilinear trend remaining in (b) after adjusting for day-of-week effects and possibly for the "outliers" you found in (c). It is your job to decide on a suitable set of basis functions [there is no "right" basis, but some are more suitable than others see, in particular, the comments in (e)].
- (e) For your fit, compute the *residuals*: the original data points (numbers of births) minus the day-of-week adjustment and the trend function you found. Recall from lecture that if one of your basis functions is a constant, the mean of the *residuals* should be zero (if it isn't, you're not doing the computations correctly). Ideally, there should not be an obvious trend in the residuals; such a trend may suggest something "missing" from your basis functions.
- (f) Discuss the function you fitted in (d) in relation to real-life factors that vary over the course of year. Is there significant seasonal variation, and why or why not?
