# Eigenvalues of Laplacians

## $\Delta, L, \tilde{\Delta}$

Today we discuss the spectral theory of graphs. Recall the Laplacian matrices:

$$\Delta = D - A \quad , \quad \Delta_{ij} = \begin{cases} d_i & \text{if} \quad i = j \\ -1 & \text{if} \quad (i,j) \in \mathcal{E} \\ 0 & \text{otherwise} \end{cases}$$

$$L = D^{-1}\Delta \quad , \quad L_{i,j} = \begin{cases} 1 & \text{if} \quad i = j \text{ and } d_i > 0 \\ -\frac{1}{d(i)} & \text{if} \quad (i,j) \in \mathcal{E} \\ 0 & \text{otherwise} \end{cases}$$

$$\tilde{\Delta} = D^{-1/2}\Delta D^{-1/2} \quad , \quad \tilde{\Delta}_{i,j} = \begin{cases} 1 & \text{if} \quad i = j \text{ and } d_i > 0 \\ -\frac{1}{\sqrt{d(i)d(j)}} & \text{if} \quad (i,j) \in \mathcal{E} \\ 0 & \text{otherwise} \end{cases}$$

# Eigenvalues of Laplacians

## $\Delta, L, \tilde{\Delta}$

Today we discuss the spectral theory of graphs. Recall the Laplacian matrices:

$$\Delta = D - A \quad , \quad \Delta_{ij} = \begin{cases} d_i & if \quad i = j \\ -1 & if \quad (i,j) \in \mathcal{E} \\ 0 & \quad otherwise \end{cases}$$

$$L = D^{-1}\Delta \quad , \quad L_{i,j} = \begin{cases} 1 & if \quad i = j \text{ and } d_i > 0 \\ -\frac{1}{d(i)} & if \quad (i,j) \in \mathcal{E} \\ 0 & \quad otherwise \end{cases}$$

$$\tilde{\Delta} = D^{-1/2}\Delta D^{-1/2} \quad , \quad \tilde{\Delta}_{i,j} = \begin{cases} 1 & if \quad i = j \text{ and } d_i > 0 \\ -\frac{1}{\sqrt{d(i)d(j)}} & if \quad (i,j) \in \mathcal{E} \\ 0 & \quad otherwise \end{cases}$$

Remark: $D^{-1}, D^{-1/2}$ are the pseudoinverses.

# Eigenvalues of Laplacians
## $\Delta, L, \tilde{\Delta}$

What do we know about the set of eigenvalues of these matrices for a graph $G$ with $n$ vertices?

1. $\Delta = \Delta^T \geq 0$ and hence its eigenvalues are non-negative real numbers.
2. $eigs(\tilde{\Delta}) = eigs(L) \subset [0, 2]$.
3. 0 is always an eigenvalue and its multiplicity equals the number of connected components of $G$,

$$dim\, ker(\Delta) = dim\, ker(L) = dim\, ker(\tilde{\Delta}) = \#connected\ \ components.$$

# Eigenvalues of Laplacians

## $\Delta, L, \tilde{\Delta}$

What do we know about the set of eigenvalues of these matrices for a graph $G$ with $n$ vertices?

1. $\Delta = \Delta^T \geq 0$ and hence its eigenvalues are non-negative real numbers.
2. $eigs(\tilde{\Delta}) = eigs(L) \subset [0, 2]$.
3. 0 is always an eigenvalue and its multiplicity equals the number of connected components of $G$,

$$dim\,ker(\Delta) = dim\,ker(L) = dim\,ker(\tilde{\Delta}) = \#connected\ components.$$

Let $0 = \lambda_0 \leq \lambda_1 \leq \cdots \leq \lambda_{n-1}$ be the eigenvalues of $\tilde{\Delta}$. Denote

$$\lambda(G) = \max_{1 \leq i \leq n-1} |1 - \lambda_i|.$$

Note $\sum_{i=1}^{n-1} \lambda_i = trace(\tilde{\Delta}) = n$. Hence the average eigenvalue is about 1. $\lambda(G)$ is called *the absolute gap* and measures the spread of eigenvalues away from 1.

# The spectral absolute gap

## $\lambda(G)$

The main result in [8]) says that for connected graphs w/h.p.:

$$\lambda_1 \geq 1 - \frac{C}{\sqrt{\text{Average Degree}}} = 1 - \frac{C}{\sqrt{p(n-1)}} = 1 - C\sqrt{\frac{n}{2m}}.$$

### Theorem (For class $\mathcal{G}_{n,p}$)

*Fix $\delta > 0$ and let $p > (\frac{1}{2} + \delta)log(n)/n$. Let $d = p(n-1)$ denote the expected degree of a vertex. Let $\tilde{G}$ be the giant component of the Erdös-Rényi graph. For every fixed $\varepsilon > 0$, there is a constant $C = C(\delta, \varepsilon)$, so that*

$$\lambda(\tilde{G}) \leq \frac{C}{\sqrt{d}}$$

*with probability at least $1 - Cn\exp(-(2-\varepsilon)d) - C\exp(-d^{1/4}log(n))$.*

Connectivity threshold: $p \sim \frac{log(n)}{n}$.

# The spectral absolute gap
## $\lambda(G)$

The main result in [8] says that for connected graphs w/h.p.:

$$\lambda_1 \geq 1 - \frac{C}{\sqrt{\text{Average Degree}}} = 1 - \frac{C}{\sqrt{p(n-1)}} = 1 - C\sqrt{\frac{n}{2m}}.$$

**Theorem (For class $\Gamma^{n,m}$)**

*Fix $\delta > 0$ and let $m > \frac{1}{2}(\frac{1}{2}+\delta)n\log(n)$. Let $d = \frac{2m}{n}$ denote the expected degree of a vertex. Let $\tilde{G}$ be the giant component of the Erdös-Rényi graph. For every fixed $\varepsilon > 0$, there is a constant $C = C(\delta, \varepsilon)$, so that*

$$\lambda(\tilde{G}) \leq \frac{C}{\sqrt{d}}$$

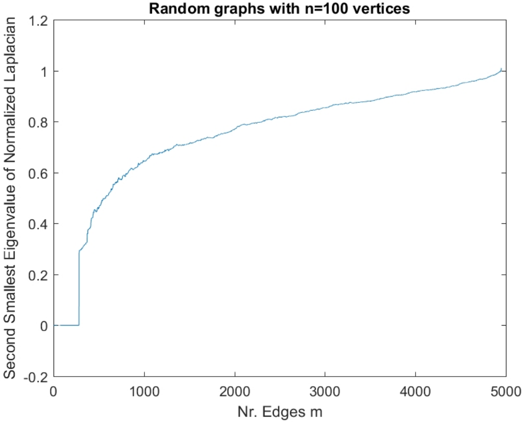
*with probability at least $1 - Cn\exp(-(2-\varepsilon)d) - C\exp(-d^{1/4}\log(n))$.*

Connectivity threshold: $m \sim \frac{1}{2}n\log(n)$.

# Numerical Results

## $\lambda_1$ for random graphs

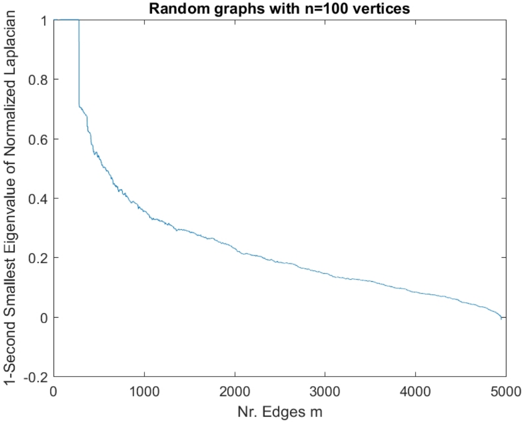
Results for $n = 100$ vertices: $\lambda_1(\tilde{G}) \approx 1 - \frac{C}{\sqrt{m}}$.



# Numerical Results

## $1 - \lambda_1$ for random graphs

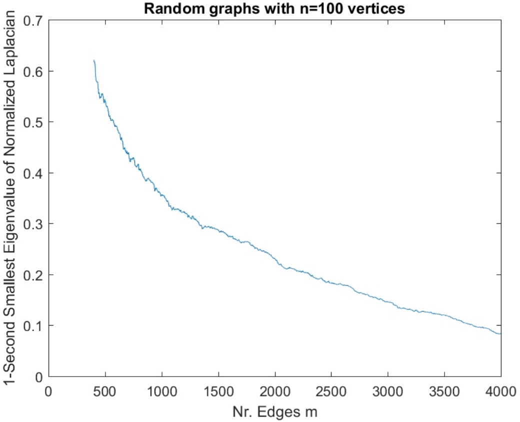
Results for $n = 100$ vertices: $\lambda_1(\tilde{G}) \approx 1 - \frac{C}{\sqrt{m}}$.



# Numerical Results

## $1-\lambda_1$ for random graphs

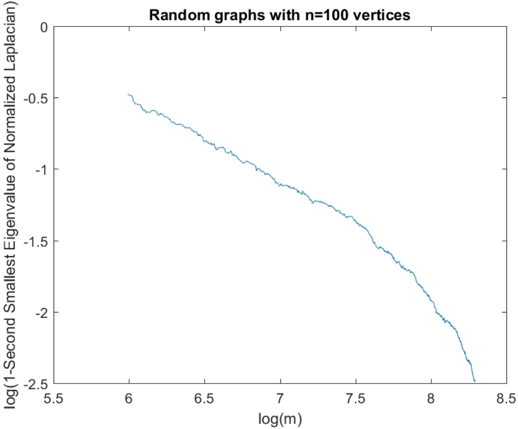
Results for $n = 100$ vertices: $\lambda_1(\tilde{G}) \approx 1 - \frac{C}{\sqrt{m}}$.



# Numerical Results

## $log(1-\lambda_1)$ vs. $log(m)$ for random graphs

Results for $n = 100$ vertices: $\lambda_1(\tilde{G}) \approx 1 - \frac{C}{\sqrt{m}}$.



# The spectral absolute gap

## Proof

How to obtain such estimates? Following [4]:
First note: $\lambda_i = 1 - \lambda_i(D^{-1/2}AD^{-1/2})$. Thus

$$\lambda(G) = \max_{1\leq i\leq n-1} |1-\lambda_i| = \|D^{-1/2}AD^{-1/2}\| = \sqrt{\lambda_{max}((D^{-1/2}AD^{-1/2})^2)}$$

Ideas:

1. For $X = D^{-1/2}AD^{-1/2}$, and any positive integer $k > 0$,
$$\lambda_{max}(X^2) = \left(\lambda_{max}(X^{2k})\right)^{1/k} \leq \left(trace(X^{2k})\right)^{1/k}$$
2. (Markov's inequality)
$$Prob\{\lambda(G) > t\} = Prob\{\lambda(G)^{2k} > t^{2k}\} \leq \frac{1}{t^{2k}}\mathbb{E}[trace(X^{2k})].$$

# The spectral absolute gap
## Proof (2)

Consider the easier case when $D = dI$ (all vertices have the same degree):

$$\mathbb{E}[(X^{2k})] = \frac{1}{d^{2k}}\mathbb{E}[trace(A^{2k})].$$

The expectation turns into numbers of $2k$-cycles and loops. Combinatorial kicks in ...

# The spectral absolute gap

## Proof (2)

Consider the easier case when $D = dI$ (all vertices have the same degree):

$$\mathbb{E}[(X^{2k})] = \frac{1}{d^{2k}}\mathbb{E}[trace(A^{2k})].$$

The expectation turns into numbers of $2k$-cycles and loops. Combinatorial kicks in ...

### Remark

*An additional "ingredient" sometimes: Bernstein's "trick" for $X \geq 0$,*

$$Prob\{X \leq t\} = Prob\{e^{-sX} \geq e^{-st}\} \leq \min_{s\geq 0} \frac{\mathbb{E}[e^{-sX}]}{e^{-st}}$$

$$= \min_{s\geq 0} e^{st} \int_0^\infty e^{-sx} p_X(x) dx$$

# The spectral absolute gap
## Proof (2)

Consider the easier case when $D = dI$ (all vertices have the same degree):

$$\mathbb{E}[(X^{2k})] = \frac{1}{d^{2k}}\mathbb{E}[trace(A^{2k})].$$

The expectation turns into numbers of $2k$-cycles and loops. Combinatorial kicks in ...

### Remark

*An additional "ingredient" sometimes: Bernstein's "trick" for $X \geq 0$,*

$$Prob\{X \leq t\} = Prob\{e^{-sX} \geq e^{-st}\} \leq \min_{s \geq 0} \frac{\mathbb{E}[e^{-sX}]}{e^{-st}}$$

$$= \min_{s \geq 0} e^{st} \int_0^\infty e^{-sx} p_X(x) dx$$

*(the "Laplace" method). It gives exponential decay instead of $\frac{1}{t}$ or $\frac{1}{t^2}$.*

# The Cheeger constant

## Partitions

Fix a graph $G = (\mathcal{V}, \mathcal{E})$ with $n$ vertices and $m$ edges. We try to find an optimal partition $\mathcal{V} = A \cup B$ that minimizes a certain quantity.
Here are the concepts:

1. For two disjoint sets of vertices $A$ abd $B$, $E(A, B)$ denotes the set of edges that connect vertices in $A$ with vertices in $B$:
$$E(A, B) = \{(x, y) \in \mathcal{E} \quad , \quad x \in A \; , \; y \in B\}.$$
2. The *volume* of a set of vertices is the sum of its degrees:
$$vol(A) = \sum_{x \in A} d_x.$$
3. For a set of vertices $A$, denote $\bar{A} = \mathcal{V} \setminus A$ its complement.

# The Cheeger constant

## $h_G$

The *Cheeger constant* $h_G$ is defined as

$$h_G = \min_{S \subset \mathcal{V}} \frac{|E(S,\bar{S})|}{min(vol(S), vol(\bar{S}))}.$$

### Remark

*It is a min edge-cut problem: This means, find the minimum number of edges that need to be cut so that the graph becomes disconnected, while the two connected components are not too small.*
*There is a similar min vertex-cut problem, where* $E(S,\bar{S})$ *is replaced by* $\delta(S)$, *the set of boundary points of* $S$ *(the constant is denoted by* $g_G$*).*

### Remark

*The graph is connected iff* $h_G > 0$.

# The Cheeger inequalities

## $h_G$ and $\lambda_1$

See [2](ch.2):

**Theorem**

*For a connected graph*

$$2h_G \geq \lambda_1 > 1 - \sqrt{1 - h_G^2} > \frac{h_G^2}{2}.$$

*Equivalently:*

$$\sqrt{2\lambda_1} > \sqrt{1 - (1 - \lambda_1)^2} > h_G \geq \frac{\lambda_1}{2}.$$

Why is it interesting: finding the exact $h_G$ is a NP-hard problem.

# The Cheeger inequalities
## Proof of upper bound

Why the upper bound: $2h_G \geq \lambda_1$?
All starts from understanding what $\lambda_1$ is:

$$\Delta 1 = 0 \rightarrow \tilde{\Delta} D^{1/2} 1 = 0$$

Hence the eigenvector associated to $\lambda_0 = 0$ is

$$g^0 = (\sqrt{d_1}, \sqrt{d_2}, \cdots, \sqrt{d_n})^T.$$

The eigenpair $(\lambda_1, g^1)$ is given by a solution of the following optimization problem:

$$\lambda_1 = \min_{h \perp g^0} \frac{\langle \tilde{\Delta} h, h \rangle}{\langle h, h \rangle}$$

In particular any $h$ so that $\langle h, g^0 \rangle = \sum_{k=1}^n h_k \sqrt{d_k} = 0$ satisfies

$$\langle \tilde{\Delta} h, h \rangle \geq \lambda_1 \|h\|^2.$$

# The Cheeger inequalities

## Proof of upper bound (2)

Assume that we found the optimal partition $(A = S, B = \bar{S})$ of $\mathcal{V}$ that minimizes the edge-cut.
Define the following particular $n$-vector:

$$h_k = \begin{cases} \frac{\sqrt{d_k}}{vol(A)} & if \quad k \in A = S \\ -\frac{\sqrt{d_k}}{vol(B)} & if \quad k \in B = \mathcal{V} \setminus S \end{cases}$$

One checks that $\sum_{k=1}^{n} h_k \sqrt{d_k} = 1 - 1 = 0$, and $\|h\|^2 = \frac{1}{vol(A)} + \frac{1}{vol(B)}$.
But:

$$\langle \tilde{\Delta} h, h \rangle = \sum_{(i,j):A_{i,j}=1} \left(\frac{h_i}{\sqrt{d_i}} - \frac{h_j}{\sqrt{d_j}}\right)^2 = |E(A,B)| \left(\frac{1}{vol(A)} + \frac{1}{vol(B)}\right)^2.$$

Thus:

$$2h_G = \frac{2|E(A,B)|}{min(vol(A), vol(B))} \geq |E(A,B)| \left(\frac{1}{vol(A)} + \frac{1}{vol(B)}\right) \geq \lambda_1.$$

# Min-cut Problems
## Initialization

The proof of the upper bound in Cheeger inequality reveals a "good" initial guess of the optimal partition:

1. Compute the eigenpair $(\lambda_1, g^1)$ associated to the second smallest eigenvalue;
2. Form the partition:

$$S = \{k \in \mathcal{V} \ \ , \ \ g^1_k \geq 0\} \ \ , \ \ \bar{S} = \{k \in \mathcal{V} \ \ , \ \ g^1_k < 0\}$$

# Min-cut Problems

## Weighted Graphs

The Cheeger inequality holds true for weighted graphs, $G = (\mathcal{V}, \mathcal{E}, W)$.

- $\Delta = D - W$, $D = diag(w_i)_{1 \leq i \leq n}$, $w_i = \sum_{j \neq i} w_{i,j}$
- $\tilde{\Delta} = D^{-1/2} \Delta D^{-1/2} = I - D^{-1/2} W D^{-1/2}$
- $eigs(\tilde{\Delta}) \subset [0, 2]$
- $h_G = \min_S \frac{\sum_{x \in S, y \in \bar{S}} W_{x,y}}{min(\sum_{x \in S} W_{x,x}, \sum_{y \in \bar{S}} W_{y,y})}$
- $2h_G \geq \lambda_1 \geq 1 - \sqrt{1 - h_G^2}$
- Good initial guess for optimal partition: Compute the eigenpair $(\lambda_1, g^1)$ associated to the second smallest eigenvalue of $\tilde{\Delta}$; set:

$$S = \{k \in \mathcal{V} \ \ , \ \ g_k^1 \geq 0\} \ \ , \ \ \bar{S} = \{k \in \mathcal{V} \ \ , \ \ g_k^1 < 0\}$$
